

On the Macroeconomic and Financial Implications of the Demographic Transition

R. Albrieu and J.M. Fanelli

CEDES, Argentina

MOTIVATION

- ✓ The main purpose of the paper is to explore the links between the demographic transition, the macroeconomy, and financial assets

- ✓ Why is it relevant to examine the demographic problems from this perspective?
 1. Bonus Stage: *financial deepening and financial stability are crucial for the second dividend to materialize*
 2. Aging Stage: *social security and health expenditures can jeopardize the solvency of the public sector and macro stability*
 3. Global Demographic Asymmetries: *capital flows are critical to profit from existing international demographic asymmetries*

- ✓ The IDRC-CEDES Project addresses point three, but it was necessary to develop a methodological framework for the case studies

METHODOLOGICAL FRAMEWORK: GOALS

- ✓ To integrate the NTA methodology with the concepts utilized in the study of macroeconomic fluctuations and aggregate financial analysis
- ✓ To identify the links and interactions between the SR, the FS, the cohort's deficits, and the aggregate representative agents' deficit
- ✓ To show that the LCD (and demographic-driven public transfers) create and destroy financial assets and impinge on asset accumulation
- ✓ To analyze the macroeconomic effects of the changes in the life cycle deficit and the demand for wealth during the bonus and aging stages
- ✓ To examine the implications for stocks (LCW, public debt, and the country's external financial position) and for stock-flow disequilibria
- ✓ To run simulations for a set of G-20 emerging countries using NTA database to show the empirical relevance of the framework

METHODOLOGICAL FRAMEWORK: RELATION WITH DIVIDENDS

$$(Y_t/N_t) = (Y_t/L_t)(L_t/N_t)$$

Second Dividend (arrow pointing to (Y_t/L_t))

First Dividend (arrow pointing to (L_t/N_t))

□ *Flows*

- NTA: LCD → Asset-Based Reallocations
- MACRO: LCD → S;I → Current Account
- FINANCE: LCD → ΔF & ΔB

□ *Stocks*

- NTA: LCW & TW → Asset Accumulation (K/L)
- MACRO: Stock/Flow disequilibria: global imbalances; debt sustainability
- FINANCE: Financial deepening; external financial position

- NTA: SR & FS; “Transitory” Effects
- MACRO: Savings/Income
- FINANCE: Structural & Scale effects

Support Ratios and Fiscal Support Ratios

Adjusted Support Ratio and Adjusted Fiscal Support Ratio

Adjusted Support Ratio is defined as follows:

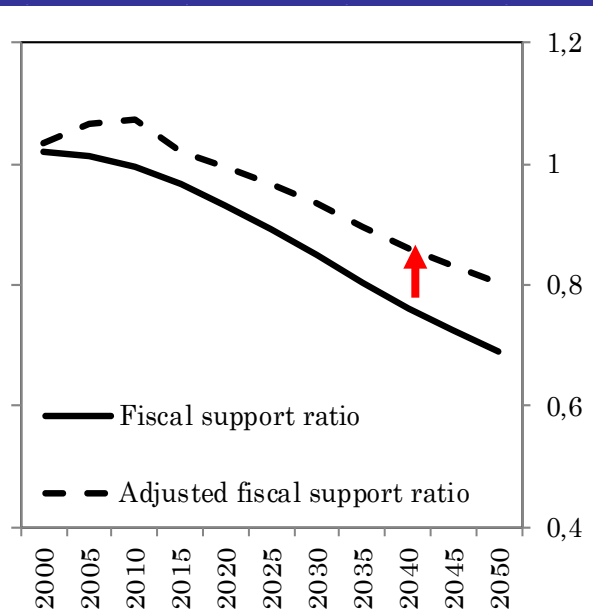

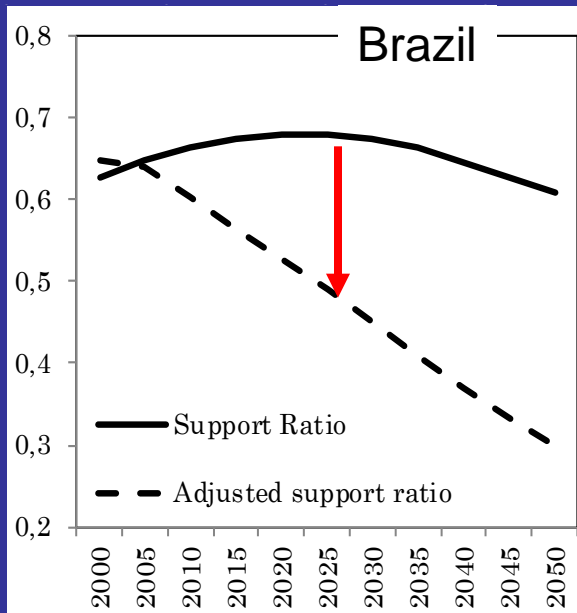

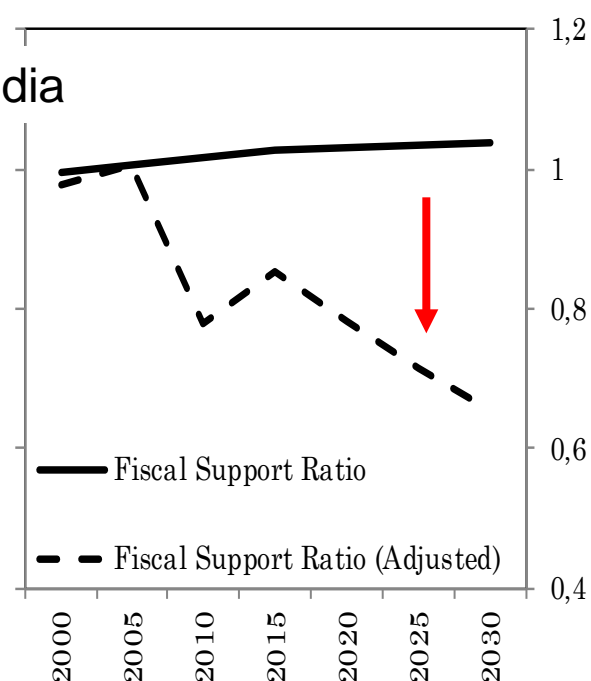

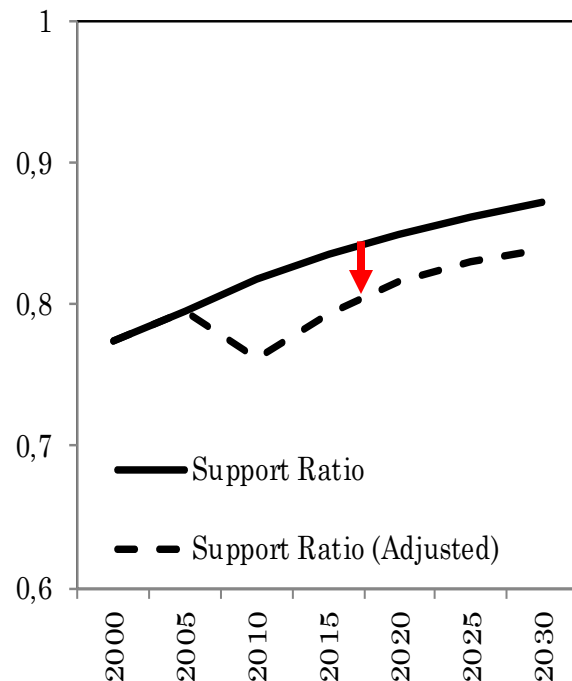

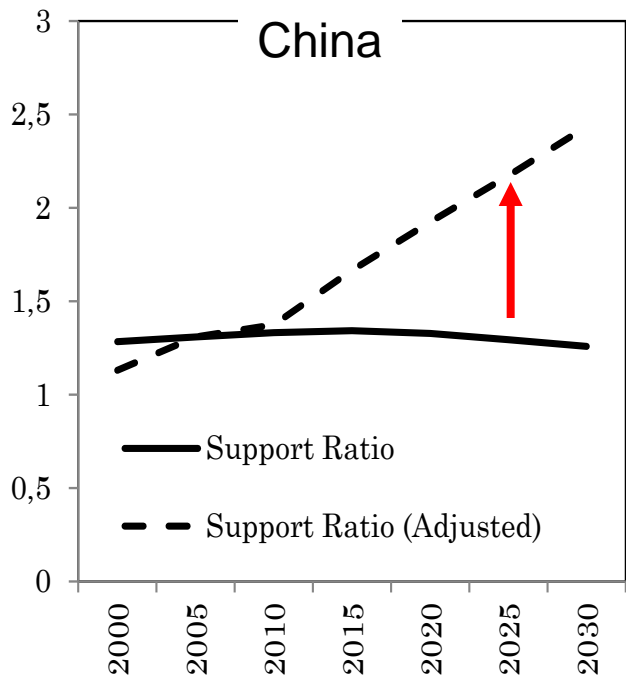

$$SRA_{t,z} = SR_{t,z} (HI_{t,z}/HC_{t,z})$$

where $HI_{t,z}$ and $HC_{t,z}$ are the proportional increase in per capita labor income and the per capita consumption between period t and $t + z$.

The Adjusted Fiscal Support Ratio is

$$FSA_{t,z} = FS_{t,z} (HT_{t,z}/HG_{t,z})$$

Where the growth in per capita taxes and per capita benefits are, respectively, $HT_{t,z}$, and $HG_{t,z}$.

Flows:

**Savings and the Life Cycle
Deficit**

From the Life Cycle Deficit to Savings

The trajectory of LCD is determined by the evolution of overall consumption and the changes in SRA:

$$\text{LCD}_{t,z} = C_{t,z} (1 - \text{SRA}_{t,z})$$

Government net transfers (τ) – which is the difference between transfers received (G) and taxes (T) from the private sector – can be expressed in terms of FSA and the evolution of public expenditures:

$$\tau_{t,z} = G_{t,z} (1 - \text{FSA}_{t,z})$$

Sectoral savings can be defined as

$$S_{p,t,z} = Y_{p,t,z} + G_{t,z} (1 - \text{FSA}_{t,z}) - C_{t,z} (1 - \text{SRA}_{t,z}) = \Delta F_{p,t,z} + \Delta B_{p,t,z} + \Delta K_{p,t,z}$$

$$S_{g,t,z} = Y_{g,t,z} - G_{t,z} (1 - \text{FSA}_{t,z}) = \Delta K_{p,t,z} + \Delta F_{g,t,z} - \Delta B_{t,z}$$

$$S_{f,t,z} = -CA_{t,z} = -\Delta F_{t,z}$$

Stocks:
Assets' Dynamics

Assets' Dynamics

Using the national accounts terminology, we define

$$\text{LCD}_{t,z} = \text{YA}_{t,z} - (\text{Sp}_{t,z} + \text{Sg}_{t,z}) = \text{YA}_{t,z} - (\text{I}_{t,z} + \text{CA}_{t,z})$$

and

$$\text{A}_{t,z} = \text{Fp}_{t,z} + \text{Fg}_{t,z} + \text{Kp}_{t,z} + \text{Kg}_{t,z}$$

Projections: Two scenarios

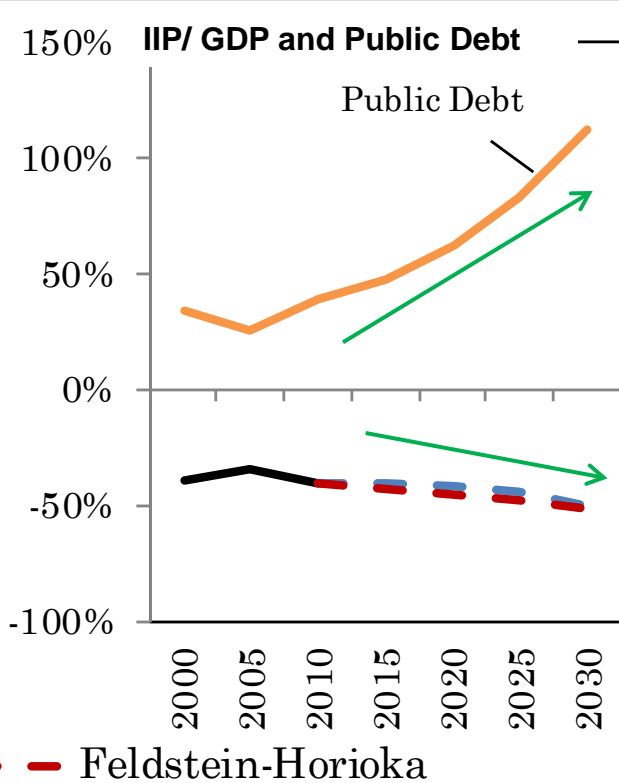

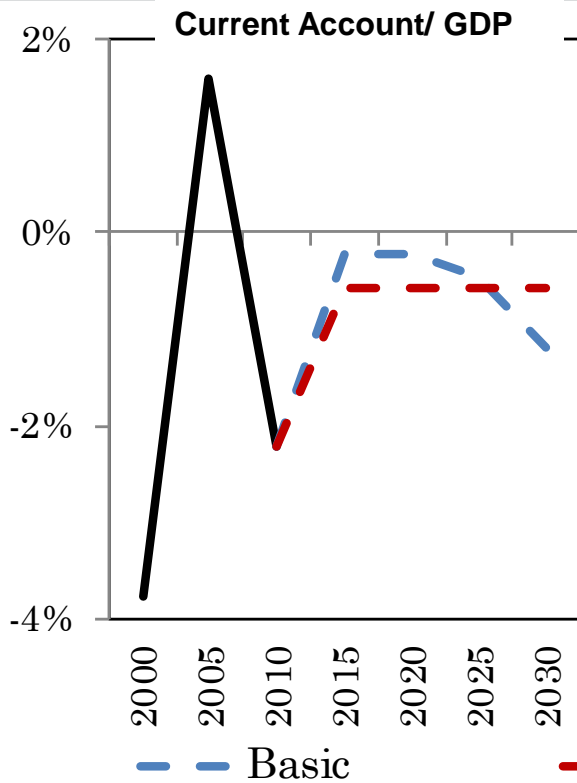

(a) Basic: unadjusted support ratios; constant investment rates

(a) Feldstein-Horioka: unadjusted support ratios; constant Current Account/GDP ratio

Stocks:

Life Cycle Wealth and Transfer Wealth

LCW and Transfer Wealth

We define the value of the life-cycle wealth that the afore-mentioned cohorts intend to demand for the planning period $t / t+Z$, as:

$$LCW_{t,Z} = \sum_{z=0}^{z=Z} C_{t,z} (1 - SRA_{t,z}) HD_{t,z} = \sum_{z=0}^{z=Z} LCD_{t,z} HD_{t,z}$$

and the “transfer wealth” (TW) that will contribute to financing LCW as:

$$TW_{t,Z} = \sum_{z=0}^{z=Z} G_{t,z} (1 - FSA_{t,z}) HD_{t,z}$$

it follows that:

$$A_{t,Z} = A_{p,t-1} + A_{g,t-1} + \sum_{z=0}^{z=Z} [YG_{t,z} + YP_{t,z}] HD_{t,z} - LCW_{t,Z}$$

Wealth Estimates
(% of 2030 GDP)

	Baseline	
	Life-cycle wealth	Transfer wealth
India	45%	55%
Brazil	565%	16%
China	-148%	n.d.

CONCLUSIONS

- ✓ **The literature on the macroeconomic effects of demography is focused on long-run growth when investment and savings are equal**
- ✓ **However, structural transformations associated with demography may give rise to macroeconomic disequilibria that can be long-lasting and difficult to manage**
- ✓ **This type of disequilibrium may preclude a country from taking advantage of the dividends or from preparing for the aging stage**

Our analysis of potential macroeconomic disequilibria indicates that the following issues should take center stage:

- ✓ **The consequences of demographic changes for fiscal flows (the fiscal deficit) and stocks (public debt)**
- ✓ **The adjusted versions of SR and FS to incorporate scale effects and macroeconomic imbalances in the analysis of the dividends**
- ✓ **The evolution of the current account and the international investment position of domestic residents**
- ✓ **The disequilibria between stocks and flows in the medium run originating in inconsistencies between the supply and demand for wealth.**

The evidence that we analyzed suggests that these types of effects are particularly difficult to manage

- ✓ **When there exist too few policy instruments to deal with the demographic transition; the availability of fiscal space is critical in this regard (Brazil and India debt stocks)**
- ✓ **When initial conditions are unfavorable (compare Brazil with China)**
- ✓ **When large countries experience sizable disequilibria because of the interaction between a low consumption rate and favorable demographics that impinge on global imbalances and capital flows (China)**

THANKS!!
